(57) **ABSTRACT**

The power supply control device in accordance with the present invention includes: a power reception terminal for receiving power; a power supply terminal for supplying power; a relay configured to make and break an electrical connection between the power reception terminal and the power supply terminal; a control circuit configured to control the relay; a power supply circuit configured to supply power to the control circuit by use of power received via the power reception terminal; and a printed wiring board. The control circuit and the power supply circuit are mounted on the printed wiring board.

**POWER SUPPLY CONTROL DEVICE****TECHNICAL FIELD**

The present invention relates to power supply control devices.

**BACKGROUND ART**

In the past, there have been provided power supply control devices that control power supply from external power sources to automobiles. The external power source is, for example, a commercial 100V AC power supply. The automobile includes a battery and a charging circuit for charging the battery, is capable of running on a motor that is driven by electrical power from the battery, and specifically is a plug-in hybrid vehicle or an electric vehicle. The power supply control device is used for supplying electrical power to the charging circuit.

A power supply control device of this kind includes a relay inserted in a power supply path from the external power source to a load (charging circuit), a control circuit that controls turning on/off of the relay, and a power circuit for generating power for the control circuit. The control circuit controls the relay to be turned off, according to a signal input from the outside or when an abnormality such as an electric leakage is detected, for example.

Conventionally, the control circuit and the power circuit are mounted on different printed wiring boards (see document 1 [JP 2011-135653 A]).

However, in the case where the control circuit and the power circuit are mounted on the different printed wiring boards, as described above, it is necessary to provide conductors (such as pins or electric cables) connecting the printed wiring board on which the control circuit is mounted to the printed wiring board on which the power circuit is mounted. When such conductors are provided, there is a possibility that poor or bad connection with the printed wiring boards will occur at both ends of the conductors, and thus the possibility of such poor connection occurring as a whole is relatively high.

**SUMMARY OF INVENTION**

The present invention has been made in view of the above-described problems, and an object of the present invention is to provide a power supply control device in which poor connection is not likely to occur.

The power supply control device of the first aspect in accordance with the present invention includes: a power reception terminal for receiving power; a power supply terminal for supplying power; a relay configured to make and break an electrical connection between the power reception terminal and the power supply terminal; a control circuit configured to control the relay; a power supply circuit configured to supply power to the control circuit by use of power received via the power reception terminal; and a printed wiring board. The control circuit and the power supply circuit are mounted on the printed wiring board.

According to the power supply control device of the second aspect in accordance with the present invention, in addition to the first aspect, the power supply control device further includes an electrical circuit and a block. The electrical circuit is electrically connecting the power reception terminal and the power supply terminal. The block holds the power reception terminal, the power supply terminal, the relay, the printed wiring board, and the electrical circuit. The relay is config-

2

ured to make and break the electrical connection between the power reception terminal and the power supply terminal by opening and closing the electrical circuit. The block has a first end and a second end respectively defining opposite ends in a first direction, and a third end and a fourth end respectively defining opposite ends in a second direction perpendicular to the first direction. The power reception terminal and the power supply terminal are positioned at the first end and the second end, respectively. The electrical circuit is positioned closer to the third end than the fourth end such that a circuit accommodating space is formed closer to the third end than the fourth end. The control circuit and the power supply circuit are positioned in the circuit accommodating space.

According to the power supply control device of the third aspect in accordance with the present invention, in addition to the second aspect, the block has a fifth end and a sixth end respectively defining opposite ends in a third direction perpendicular to each of the first direction and the second direction. The printed wiring board has a mounting surface on which the control circuit and the power supply circuit are mounted. The printed wiring board is positioned closer to the sixth end than the fifth end such that the mounting surface faces the fifth end.

According to the power supply control device of the fourth aspect in accordance with the present invention, in addition to the third aspect, the block includes a relay accommodating space in which the relay is positioned. The relay accommodating space is positioned closer to the fourth end than the third end.

According to the power supply control device of the fifth aspect in accordance with the present invention, in addition to the fourth aspect, the block includes a supporting member supporting the relay. The supporting member is positioned closer to the sixth end than the fifth end and defines a bottom of the relay accommodating space. At least one part of the electrical circuit is embedded in the supporting member.

According to the power supply control device of the sixth aspect in accordance with the present invention, in addition to the fourth or fifth aspect, the block includes a partition. The partition is interposed between the circuit accommodating space and the relay accommodating space.

According to the power supply control device of the seventh aspect in accordance with the present invention, in addition to the sixth aspect, the block includes a first side wall defining the first end, a second side wall defining the second end, a third side wall defining the third end, and a fourth side wall defining the fourth end. The circuit accommodating space is defined as a space enclosing by the first side wall, the second side wall, the third side wall, and the partition. The relay accommodating space is defined as a space enclosing by the first side wall, the second side wall, the fourth side wall, and the partition.

According to the power supply control device of the eighth aspect in accordance with the present invention, in addition to any one of the first to seventh aspects, the power reception terminal and the power supply terminal are positioned on a straight line extending in the first direction.

According to the power supply control device of the ninth aspect in accordance with the present invention, in addition to any one of the first to eighth aspects, the power reception terminal is to be electrically connected to an external power source. The power supply terminal is to be electrically connected to a charging circuit for charging a battery of an automobile.

**BRIEF DESCRIPTION OF THE DRAWINGS**

FIG. 1 is a block diagram illustrating a power supply control device of one embodiment in accordance with the present invention;

3

FIG. 2 is an exploded perspective view illustrating a primary part of the above power supply control device;

FIG. 3 is a perspective view illustrating conductors to be embedded with insert molding in a first block of the above power supply control device;

FIG. 4 is a perspective view illustrating a state in which a printed wiring board is detached from the primary part;

FIG. 5 is a perspective view illustrating the primary part;

FIG. 6 is a perspective view illustrating conductors to be embedded with insert molding in a second block of the above power supply control device;

FIG. 7 is an exploded perspective view illustrating the above power supply control device; and

FIG. 8 is a plan view illustrating the above power supply control device;

FIG. 9 is a front view illustrating the above power supply control device; and

FIG. 10 is a bottom view illustrating the above power supply control device.

### DESCRIPTION OF EMBODIMENTS

As shown in FIG. 1, the power supply control device of one embodiment in accordance with the present invention includes a set of power reception conductors (in the present embodiment, a pair of power reception conductors) **21** to be electrically connected to an external power source (not shown) and a set of power supply conductors (in the present embodiment, a pair of power supply conductors) **22** to be electrically connected to a charging circuit of an automobile (not shown) that includes a battery and a charging circuit to charge the battery. The power reception conductors **21** and the power supply conductors **22** are provided one each for line (L) and neutral (N).

In summary, the power supply control device of the present embodiment includes the set of (two) power reception conductors **21** for receiving power, and the set of (two) power supply conductors **22** for supplying power. In the following explanation, a suffix "L" is attached to components regarding the line (L) and a suffix "N" is attached to components regarding the neutral (N), if necessary.

As shown in FIG. 3, each of the set of power reception conductors **21** includes a power reception terminal **211**, a connection terminal (first connection terminal) **212**, and an interconnecting part **213** electrically interconnecting the power reception terminal **211** and the connection terminal **212**.

The power reception terminal **211** is used for receiving power. For example, the power reception terminal **211** is to be electrically connected to an external power source. The power reception terminal **211** has a shape allowing mechanical connection with a contact terminal **711** of a predetermined plug (in the present embodiment, a device-side plug **71** of a power supply-side cable **7**). The first connection terminal **212** is electrically connected to a corresponding one of the set of power supply conductors **22**.

As shown in FIG. 3, each of the set of power supply conductors **22** includes a power supply terminal **221**, a connection terminal (second connection terminal) **222**, and an interconnecting part **223** electrically interconnecting the power supply terminal **221** and the connection terminal **222**.

The power supply terminal **221** is used for supplying power. For example, the power supply terminal **221** is to be electrically connected to a charging circuit for charging a battery of an automobile. The power supply terminal **221** has a shape allowing mechanical connection with a contact terminal **811** of a predetermined plug (in the present embodi-

4

ment, a device-side plug **81** of a load-side cable **8**). The second connection terminal **222** is electrically connected to a corresponding one of the set of power reception conductors **21**.

Moreover, the power supply control device of the present embodiment includes relays **11**, one for each polarity that open and close respective electrical connections between the power reception conductors **21** and the power supply conductors **22**. In brief, the power supply control device of the present embodiment includes a set of relays (in the present embodiment, a pair of relays) **11**. The set of (two) relays **11** make and break the electrical connections between the power reception terminals **211** and the power supply terminals **221**, respectively. For example, each of the relays **11** is constituted by known electromagnetic relays.

Furthermore, the power supply control device of the present embodiment includes a control circuit **12** configured to control the relays **11** and a power circuit **13** configured to generate operating power for the control circuit **12**. The control circuit **12** and the power circuit **13** are mounted on the same printed wiring board **50** (see FIG. 2).

The power circuit **13** receives power from the external power source via the power reception conductors **21** and generates power for the control circuit **12**. The power supply circuit **13** is configured to supply power to the control circuit **12** by use of power received via the power reception terminal **211**. For example, the power circuit **13** converts electrical power supplied by the external power source (100V AC power, for example) to electrical power that is suitable for the operation of the control circuit **12** (DC power of predetermined voltage, for example), and supplies the power to the control circuit **12**. This kind of power circuit **13** can be realized by a known AC-DC converter, for example.

The control circuit **12** is electrically connected to control terminals (that is, the terminals of electromagnet devices **112** that drive contact devices **111** of the relays **11**) of the relays **11** via a pair of conductors (hereinafter referred to as "driving conductor") **41** (**41A** and **41B**). The control circuit **12** drives (controls) the relays **11** with electrical signals input to the relays **11** via the driving conductors **41**.

The conductors **41** (**41A** and **41B**) includes first terminals **411** (**411A** and **411B**), second terminals **412** (**412A** and **412B**), and third terminals **413** (**413A** and **413B**), respectively.

As shown in FIG. 4, the electromagnet device **112** of the relay **11L** is connected between the first terminals **411A** and **411B**. The electromagnet device **112** of the relay **11N** is connected between the second terminals **412A** and **412B**.

Note that, the third terminals **413A** and **413B** are connected to the control circuit **12**.

Moreover, the power supply control device of the present embodiment includes a first grounding conductor **31** used as protective earth (PE).

As shown in FIG. 3, the first grounding conductor includes a first grounding terminal **311** for receiving power, a second grounding terminal **312** for supplying power, and a third grounding terminal **313** for detection of an electrical leakage.

The control circuit **12** and the power circuit **13** are electrically connected to the first grounding conductor **31**.

Furthermore, the power supply control device of the present embodiment includes a conductor (also designated by "C" in FIG. 1, hereinafter referred to as "first signal conductor") **42** that is to be electrically connected to the charging circuit.

The control circuit **12** controls the relays **11** according to an electrical signal (so-called CPLT signal) that is input via the first signal conductor **42**.

5

Moreover, the power supply control device of the present embodiment includes a pair of conductors (also designated by “TH1” and “TH2” in FIG. 1, hereinafter referred to as “second signal conductors”) 43 to receive an output of a thermistor (not shown) provided to an external power source.

The control circuit 12 turns off the relays 11 when receiving a signal indicative of an abnormally high temperature via the second signal conductors 43.

The conductors 21, 22, 31, 41, 42, and 43 are made of a metal plate as shown in FIG. 3, and, as shown in FIGS. 2 and 4, are held by (fixed to) a block (first block) 51 made of synthetic resin with insert molding.

For example, each of the set of power reception conductors 21 is embedded in the first block 51 such that the power reception terminal 211 and the first connection terminal 212 are exposed. Each of the set of power supply conductors 22 is embedded in the first block 51 such that the power supply terminal 221 and the second connection terminal 222 are exposed. The first grounding conductor 31 is embedded in the first block 51 such that the first grounding terminal 311, the second grounding terminal 312, and the third grounding terminal 313 are exposed.

The relays 11 and the printed wiring board 50 are fixed to the first block 51. The printed wiring board 50 is positioned such that a mounted surface 50A thereof faces the first block 51, and an insulation sheet 53 made of an insulating material such as synthetic resin is inserted between the printed wiring board 50 and the first block 51. The mounting surface 50A is defined by a surface on which the control circuit 12 and the power supply circuit 13 (electronic components of the control circuit 12 and the power supply circuit 13) are mounted.

Hereinafter, A, B, C, D, E, and F directions in FIG. 2 are referred to as upward, downward, left, right, forward, and rearward directions of the power supply control device, respectively. That is, the printed wiring board 50 is attached to a lower side of the first block 51 with the mounted surface 50A being oriented in the upward direction.

When viewed in an upward and downward direction, a whole of the first block 51 has a rectangular shape with a lengthwise direction extending along a forward and rearward direction. For example, the first block 51 has a rectangular frame shape. The first block 51 includes a first side wall 51E and a second side wall 51F facing each other in a first direction (lengthwise direction, which is identical to a direction parallel to the E and F directions in FIG. 2) and a third side wall 51D and a fourth side wall 51C facing each other in a second direction (width direction, which is identical to a direction parallel to the C and D directions in FIG. 2) perpendicular to the first direction. Further, the first block 51 includes a first open end 51A and a second open end 51B respectively defining opposite ends in a third direction (thickness direction, which is identical to a direction parallel to the A and B directions in FIG. 2) perpendicular to each of the first direction and the second direction.

In summary, the first block 51 has the first side wall (first end) 51E and the second side wall (second end) 51F respectively defining the opposite ends in the first direction (lengthwise direction, which is identical to a direction parallel to the E and F directions in FIG. 2), and the third side wall (third end) 51D and the fourth side wall (fourth end) 51C respectively defining the opposite ends in the second direction (width direction, which is identical to a direction parallel to the C and D directions in FIG. 2). Further, the first block has the first open end (fifth end) 51A and the second open end (sixth end) 51B respectively defining the opposite ends in the third direction (thickness direction, which is identical to a direction parallel to the A and B directions in FIG. 2).

6

As shown in FIGS. 4 and 5, the first block 51 is provided in a lower surface thereof with a housing recess 510 for accommodating the printed wiring board 50.

Provided on an inner bottom surface of the housing recess 510 are a plurality of (two, in the drawings) positioning protrusions 511. The printed wiring board 50 is positioned by inserting the positioning protrusions 511 into respective positioning holes 501 of the printed wiring board 50.

Further, provided near four corners of the inner bottom surface of the housing recess 510 are screw receiving portions 512 each formed into a cylindrical shape and including a screw hole opening downward (upward in FIG. 4).

The printed wiring board 50 is fixed to the first block 51 by screwing four screws 54 into the screw receiving portions 512 via screw passing holes 502 of the printed wiring board 50 respectively.

Furthermore, on the printed wiring board 50, two light-emitting diodes (not shown) are mounted side by side in the forward and rearward direction. The two light-emitting diodes are controlled by the control circuit 12 and used for displaying the conduction state and announcing abnormality.

The control circuit 12 announces abnormality (specifically, contact welding at relay 11) by lighting one of the light-emitting diodes, upon detecting conduction in any of the relays 11 even though the relays 11 are controlled to be turned off.

The first block 51 has two window holes 514 that allow passage of light from the light-emitting diodes one-by-one.

Further, the power supply control device of the present embodiment includes a light guide 55 that is made of a light transmissive (transparent or translucent) material (such as acrylic resin) and guides light from the light-emitting diodes.

The light guide 55 includes a main body portion 551 and leg portions 552. The main body portion 551 has a shape that is long in the forward and rearward direction and flat in the upward and downward direction, and the main body portion 551 is placed on an upper side of the first block 51. The leg portions 552 are protruding downward from the main body portion 551 and are to be inserted in the window holes 514 of the first block 51, respectively.

Furthermore, on an upper surface of the first block 51, swage protrusions 515 that protrude upward are provided at positions between which the two window holes 514 are positioned in the forward and rearward direction.

The light guide 55 is provided in respective opposite ends in the forward and rearward direction with swage holes 553. The light guide 55 is fixed to the first block 51 by inserting the swage protrusions 515 into the respective swage holes 553 and then swaging the swage protrusions 515.

Moreover, the power supply control device of the present embodiment includes a zero-phase current transformer 14 that is stuck on the upper surface of the first block 51 with double-sided tape 57 (see FIG. 2).

Furthermore, the power supply control device of the present embodiment includes a set of intermediate conductors (in the present embodiment, a pair of intermediate conductors) 23 and a second grounding conductor 32. The pair of intermediate conductors 23 are in physical and electrical contact with the respective power reception conductors 21. The second grounding conductor 32 is in physical and electrical contact with the first grounding conductor 31.

Each of the set of (two) intermediate conductors 23 includes a connection terminal (third connection terminal) 231 and a connection terminal (fourth connection terminal) 232. The third connection terminals 231 of the set of intermediate conductors 23 are electrically connected to the first connection terminals 212 of the set of power reception con-

ductors **21**, respectively. The set of relays **11** (contact devices **111**) are interposed between the fourth connection terminals **232** of the set of intermediate conductors **23** and the second connection terminals **222** of the set of power supply conductors **22**, respectively.

The second grounding conductor **32** includes a fourth grounding terminal **321** and a fifth grounding terminal **322**. The fourth grounding terminal **321** is electrically connected to the third grounding terminal **313** of the first grounding conductor **31**. The fifth grounding terminal **322** is electrically connected to the control circuit **12**.

As shown in FIG. 6, each of the intermediate conductors **23** and the second grounding conductor **32** is made of a belt-shaped metal plate, and has a U shape as a whole in which a center portion thereof is turned such that a thickness direction thereof is identical to the upward and rearward direction and both ends thereof are bent downward.

The intermediate conductors **23** and the second grounding conductor **32** are embedded in the second block **52** of synthetic resin by insert molding so as to be securely insulated from each other and integrated.

For example, each of the set of intermediate conductors **23** is embedded in the second block **52** such that the third connection terminal **231** and the fourth connection terminal **232** are exposed. The second grounding conductor **32** is embedded in the second block **52** such that the fourth grounding terminal **321** and the fifth grounding terminal **322** are exposed.

The second block **52** is connected to the first block **51** by engaging the second block **52** and the first block **51** with each other, for example, such that the zero-phase current transformer **14** is between the first block **51** and the second block **52**. In the power supply control device of the present embodiment, the first block **51** and the second block **52** constitute a body block **5**.

The zero-phase current transformer **14** positioned between the first block **51** and the second block **52** to allow the set of intermediate conductors **23** to pass through an inside of the zero-phase current transformer **14**. Further, the second grounding conductor **32** is positioned to pass through the inside of the zero-phase current transformer **14**.

Moreover, a set of connection conductors (in the present embodiment, two connection conductors) **24** made of a metal plate are fixed to the first block **51** by insert molding. Each of the connection conductors **24** has one end to be electrically connected to the contact of corresponding one of the relays **11** and the other end to be in physical and electrical contact with corresponding one of the intermediate conductors **23**.

Each of the set of connection conductors **24** includes a connection terminal (fifth connection terminal) **241** and a connection terminal (sixth connection terminal) **242**. Each of the set of connection conductors **24** is embedded in the first block **51** such that the fifth connection terminal **241** and the sixth connection terminal **242** are exposed. The fourth connection terminals **232** of the set of intermediate conductors **23** are electrically connected to the fifth connection terminals **241** of the set of connection conductors **24**, respectively. The set of relays **11** (the contact devices **111** of the set of relays **11**) are interposed between the sixth connection terminals **242** of the set of connection conductors **24** and the second connection terminals **222** of the set of power supply conductors **22**, respectively.

That is, the power reception conductors **21** are each electrically connected to one power supply conductor **22** via one intermediate conductor **23**, one connection conductor **24**, and one relay **11**.

In summary, in the power supply control device of the present embodiment, the interconnecting part **213L**, the first connection terminal **212L**, the intermediate conductor **23L**, the connection conductor **24L**, the relay **11L** (the contact device **111** of the relay **11L**), the second connection terminal **222L**, and the interconnecting part **223L** constitute an electrical circuit **25** (**25L**) electrically connecting the power reception terminal **211L** and the power supply terminal **221L**. The interconnecting part **213N**, the first connection terminal **212N**, the intermediate conductor **23N**, the connection conductor **24N**, the relay **11N** (the contact device **111** of the relay **11N**), the second connection terminal **222N**, and the interconnecting part **223N** constitute an electrical circuit **25** (**25N**) electrically connecting the power reception terminal **211N** and the power supply terminal **221N**.

The electrical connection between the power reception conductor **21** and the power supply conductor **22** is opened and closed depending on opening and closing of the electrical connection between the connection conductor **24** and the power supply conductor **22** by the relay **11**. In brief, the relay **11** is configured to make and break the electrical connection between the power reception terminal **211** and the power supply terminal **221** by opening and closing the electrical circuit **25**.

In the power supply control device of the present embodiment, the first block **51** holds the power reception terminals **211**, the power supply terminals **221**, the relays **11**, the printed wiring board **50**, and the electrical circuit **25**.

As shown in FIG. 2, the power reception terminal **211** and the power supply terminal **221** are positioned at the first side wall (first end, which is identical to the front end in FIG. 2) **51E** and the second side wall (second end, which is identical to the rear end) **51F**, respectively. Especially, the power reception terminal **211** and the power supply terminal **221** are positioned on a straight line extending in the first direction (lengthwise direction of the first block **51**, which is identical to a direction parallel to the E and F directions in FIG. 2).

As shown in FIGS. 3 and 4, each electrical circuit **25** is positioned closer to the third end (third side wall) **51D** than the fourth end (fourth side wall) **51C** such that a circuit accommodating space **517** is formed closer to the third end (third side wall) **51D** than the fourth end (fourth side wall) **51C**.

For example, each power reception conductor **21** is formed such that the power reception terminal **211** is positioned at the first side wall **51E** and the first connection terminal **212** is positioned closer to the fourth side wall **51C** than the third side wall **51D**. Each power supply conductor **22** is formed such that the power supply terminal **221** is positioned at the second side wall **51F** and the second connection terminal **222** is positioned closer to the fourth side wall **51C** than the third side wall **51D**. The first grounding conductor **31** is formed such that the first grounding terminal **311** and the second grounding terminal **312** are positioned at the first side wall **51E** and the second side wall **51F** respectively and a part interconnecting the first grounding terminal **311** and the second grounding terminal **312** is positioned closer to the fourth side wall **51C** than the third side wall **51D**. Each intermediate conductor **23**, each connection conductor **24**, and the second grounding conductor **32** are positioned closer to the fourth side wall **51C** than the third side wall **51D**. Accordingly, the circuit accommodating space **517** is formed closer to the third end (third side wall) **51D** than the fourth end (fourth side wall) **51C**.

The circuit accommodating space **517** is defined as a space for accommodating the control circuit **12** and the power supply circuit **13** (the electronic components of the control circuit

12 and the power supply circuit 13). The printed wiring board 50 is positioned closer to the sixth end (second open end) 51B than the fifth end (first open end) 51A such that the mounting surface 50A faces the fifth end (first open end) 51A. Accordingly, the control circuit 12 and the power supply circuit 13 are in the circuit accommodating space 517.

As shown in FIG. 2, the first block 51 includes a relay accommodating space 518 in which the relays 11 are positioned. The relay accommodating space 518 is positioned closer to the fourth end (fourth side wall) 51C than the third end (third side wall) 51D. In the power supply control device of the present embodiment, the set of relays 11 are accommodated in the relay accommodating space 518 to be arranged side by side in the lengthwise direction of the first block 51.

Further, as shown in FIGS. 2 and 3, the first block 51 includes a supporting member 58 supporting the relays 11. The supporting member 58 has a flat plate shape, for example. The supporting member 58 is positioned closer to the sixth end (second open end) 51B than the fifth end (first open end) 51A and defines a bottom of the relay accommodating space 518. The power supply conductor 22 and the connection conductor 24 which are part of the electrical circuit 25 are embedded in the supporting member 58 partially. In brief, at least one part of each electrical circuit 25 is embedded in the supporting member 58.

Furthermore, as shown in FIGS. 2 and 3, the first block 51 includes a partition 59. The partition 59 is interposed between the circuit accommodating space 517 and the relay accommodating space 518. In brief, the partition 59 divides an internal space of the first block 51 into the circuit accommodating space 517 and the relay accommodating space 518. For example, the partition 59 has a flat plate shape. The circuit accommodating space 517 is defined as a space enclosing by the first side wall 51E, the second side wall 51F, the third side wall 51D, and the partition 59. The relay accommodating space 518 is defined as a space enclosing by the first side wall 51E, the second side wall 51F, the fourth side wall 51C, and the partition 59.

The zero-phase current transformer 14 has a ring shape and is oriented such that an axial direction thereof is identical to the upward and downward direction. The intermediate conductors 23 and the second grounding conductor 32 are inserted in the zero-phase current transformer 14. In a state in which an electric leakage has not occurred, since magnetic fields generated by the respective intermediate conductors 23 cancel each other, an induction current is not generated in the zero-phase current transformer 14. When an electric leakage occurs, the two magnetic fields fail to cancel each other and thus an induction current is generated in the zero-phase current transformer 14.

The control circuit 12 determines whether or not an electric leakage has occurred based on the induction current, and turns off the relays 11 upon determining that an electric leakage has occurred (that is, when the electric leakage has been detected). In brief, the control circuit 12 is configured to, upon detecting an electrical leakage by the zero-phase current transformer 14, control the set of relays 11 to break the electrical connections between the set of intermediate conductors 23 and the set of power supply conductors 22.

Moreover, as shown in FIG. 1, the control circuit 12 is electrically connected to one of the connection conductors 24 so as to enable performing an operation test of the zero-phase current transformer 14 by applying a current for simulating the electric leakage.

As shown in FIGS. 7 to 10, the power supply control device of the present embodiment includes a housing 6 configured to

accommodate the first block 51 to which the printed wiring board 50, the relays 11, the zero-phase current transformer 14, the second block 52, and the light guide 55 are attached.

The housing 6 includes a body 61 and a cover 62. The body 61 is provided in a lower surface with a housing recess 610 for accommodating the first block 51. The cover 62 is coupled to a lower side of the body 61 to cover the housing recess 610.

The body 61 is provided at respective two portions positioned above the leg portions 552 of the light guide 55 with two display windows 613 allowing passage of light from the light emitting diodes. The display windows 613 are through holes filled with light transmissive resin, for example.

The first block 51 is provided in respective four corners when viewed in the upward and downward direction with screw insertion holes 513. Each of the screw insertion holes 513 has a ring-shape and allows insertion of screws 63 for fixing the first block 51 to the body 61 by screwing.

The first block 51 is fixed to the housing 6 (body 61). In contrast, the second block 52 is fixed to the opposite surface of the first block 51 from the cover 62. Consequently, the second block 52 is fixed to the first block 51 but is not fixed to the housing 6 directly. Besides, a method of fixing the first block 51 to the housing 6 is not limited to screwing.

Further, interposed between a lower periphery of the housing recess 610 of the body 61 and the cover 62 is a packing 64 that has a ring-shape and is made of a soft material such as elastomer.

Fixing the cover 62 to the body 61 is achieved by screwing six screws 65 into the body 61 via respective screw insertion holes 621 of the cover 62.

Also, the cover 62 includes a ventilation hole 622 that communicates to the housing recess 610 of the body 61.

Moreover, stuck to a lower surface of the cover 62 are an inner pressure adjusting sheet 69 covering the ventilation hole 622 and an inner pressure adjusting sheet cover 66 covering the inner pressure adjusting sheet 69. The inner pressure adjusting sheet 69 is made of a known porous material and ensures waterproofness and dust proofness along with breathability.

Further, stuck to the lower surface of the cover 62 are labels 67 and 68 describing various kinds of information.

The body 61 is provided at the front end thereof with a power supply connection portion 611 that has a cylinder-shape and connects an inside and an outside of the housing recess 610 of the body 61. Also, the body 61 is provided at a rear end thereof with a load connection portion 612 that has a cylinder-shape and connects the inside and the outside of the housing recess 610 of the body 61.

Each of the power reception conductors 21, the first grounding conductor 31, and the second signal conductors 43 has a front end portion, which is exposed inside the power supply connection portion 611 while a thickness direction thereof is identical to the upward and downward direction.

The first block 51 is provided at a front end (first side wall) 51E thereof with a protrusion 516 that has a ring-shape and is inserted in the power supply connection portion 611. Interposed between an outer periphery of this protrusion 516 and an inner surface of the body 61 is an O-ring 56 made of a soft material such as elastomer.

Besides, an electrical connection between the power supply control device of the present embodiment and the external power source is made via a power supply-side cable 7. The power supply-side cable 7 is provided at one end with a device-side plug 71 to be fitted into the power supply connection portion 611, and is provided at the other end with a power supply-side plug 72 to be inserted in and connected to an outlet (not shown) of the external power source.

## 11

The device-side plug **71** of the power supply-side cable **7** includes five contact terminals **711** that are kept in physical and electrical contact with the power reception conductors **21**, the first grounding conductor **31**, and the second signal conductors **43**, respectively, while the device-side plug **71** is fitted into the power supply connection portion **611**.

Each of the contact terminals **711** is clip-shaped metal plate and has portions for elastically holding corresponding one of the conductors **21**, **31**, and **43** therebetween in the thickness direction, for example.

The power supply-side cable **7** has electric wires (not shown) which include a line electric wire and a neutral electric wire to be electrically connected to the power reception conductors **21** via the contact terminals **711** respectively.

The device-side plug **71** of the power supply-side cable **7** is provided with a latch mechanism (not shown) that prevents separation thereof from the housing **6**. In FIG. 7, a release key **718** for releasing the latching by the latch mechanism is depicted.

Each of the power supply conductors **22**, the first grounding conductor **31**, and the first signal conductor **42** has a rear end portion, which is exposed inside the load connection portion **612** while a thickness direction thereof is identical to the upward and downward direction.

Further, an electrical connection between the power supply control device of the present embodiment and the charging circuit of an automobile is achieved via a load-side cable **8**. The load-side cable **8** is provided at one end with a device-side plug **81** to be fitted in the load connection portion **612**, and is provided at the other end with a load-side plug **82** to be inserted in and connected to a socket (not shown) of the automobile.

The device-side plug **81** of the load-side cable **8** includes the four contact terminals **811** that are kept in physical and electrical contact with the power supply conductors **22**, the first grounding conductor **31**, and the first signal conductor **42**, respectively, while the device-side plug **81** is fitted into the load connection portion **612**.

Each of the contact terminals **811** is a clip-shaped metal plate, and has portions for elastically holding corresponding one of the conductors **22**, **31**, and **42** therebetween in the thickness direction, for example.

The load-side cable **8** has electric wires (not shown) including a line electric wire and a neutral electric wire to be electrically connected to the power supply conductors **22** via the contact terminals **811**, respectively.

As described above, the power supply control device of the present embodiment includes: the power reception conductor **21** to be electrically connected to an external power source; the power supply conductor **22** to be electrically connected to a charging circuit of an automobile including a battery and the charging circuit for charging the battery; the relay **11** configured to make and break the electrical connection between the power reception conductor **21** and the power supply conductor **22**; the control circuit **12** configured to control the relay **11**; the power supply circuit **13** configured to receive power from the external power source via the power reception conductor **21** and generate power for the control circuit **12**; and the printed wiring board **50** on which the control circuit **12** and the power circuit **13** are mounted.

In other words, the power supply control device of the present embodiment involves the following first feature.

According to the first feature, the power supply control device includes: the power reception terminal **211** for receiving power; the power supply terminal **221** for supplying power; the relay **11** configured to make and break the electrical connection between the power reception terminal **211** and

## 12

the power supply terminal **221**; the control circuit **12** configured to control the relay **11**; the power supply circuit **13** configured to supply power to the control circuit **12** by use of power received via the power reception terminal **211**; and the (single) printed wiring board **50**. The control circuit **12** and the power supply circuit **13** are mounted on the printed wiring board **50**.

Additionally, the power supply control device of the present embodiment involves the following second to ninth features. Note that, the second to ninth features are optional.

According to the second feature, in addition to the first feature, the power supply control device further includes the electrical circuit **25** and the block (first block) **51**. The electrical circuit **25** is electrically connecting the power reception terminal **211** and the power supply terminal **221**. The block **51** holds the power reception terminal **211**, the power supply terminal **221**, the relay **11**, the printed wiring board **50**, and the electrical circuit **25**. The relay **11** is configured to make and break the electrical connection between the power reception terminal **211** and the power supply terminal **221** by opening and closing the electrical circuit **25**. The block **51** has the first end **51E** and the second end **51F** respectively defining opposite ends in the first direction (lengthwise direction), and the third end **51D** and the fourth end **51C** respectively defining opposite ends in the second direction (width direction) perpendicular to the first direction. The power reception terminal **211** and the power supply terminal **221** are positioned at the first end **51E** and the second end **51F**, respectively. The electrical circuit **25** is positioned closer to the third end **51D** than the fourth end **51C** such that the circuit accommodating space **517** is formed closer to the third end **51D** than the fourth end **51C**. The control circuit **12** and the power supply circuit **13** are positioned in the circuit accommodating space **517**.

According to the third feature, in addition to the second feature, the block **51** has a fifth end **51A** and a sixth end **51B** respectively defining opposite ends in the third direction (thickness direction) perpendicular to each of the first direction and the second direction. The printed wiring board **50** has the mounting surface **50A** on which the control circuit **12** and the power supply circuit **13** are mounted. The printed wiring board **50** is positioned closer to the sixth end **51B** than the fifth end **51A** such that the mounting surface **50A** faces the fifth end **51A**.

According to the fourth feature, in addition to the third feature, the block **51** includes the relay accommodating space **518** in which the relay **11** is positioned. The relay accommodating space **518** is positioned closer to the fourth end **51C** than the third end **51D**.

According to the fifth feature, in addition to the fourth feature, the block **51** includes the supporting member **58** supporting the relay **11**. The supporting member **58** is positioned closer to the sixth end **51B** than the fifth end **51A** and defines a bottom of the relay accommodating space **518**. At least one part of the electrical circuit **25** is embedded in the supporting member **58**.

According to the sixth feature, in addition to the fourth or fifth feature, the block **51** includes the partition **59**. The partition **59** is interposed between the circuit accommodating space **517** and the relay accommodating space **518**.

According to the seventh feature, in addition to the sixth feature, the block **51** includes the first side wall **51E** defining the first end, the second side wall **51F** defining the second end, the third side wall **51D** defining the third end, and the fourth side wall **51C** defining the fourth end. The circuit accommodating space **517** is defined as a space enclosing by the first side wall **51E**, the second side wall **51F**, the third side wall **51D**, and the partition **59**. The relay accommodating space

## 13

**518** is defined as a space enclosing by the first side wall **51E**, the second side wall **51F**, the fourth side wall **51C**, and the partition **59**.

According to the eighth feature, in addition to any one of the first to seventh features, the power reception terminal **211** and the power supply terminal **221** are positioned on a straight line extending in the first direction.

According to the ninth feature, in addition to any one of the first to eighth features, the power reception terminal **211** is to be electrically connected to an external power source. The power supply terminal **221** is to be electrically connected to a charging circuit for charging a battery of an automobile.

According to the above configuration, the control circuit **12** and the power circuit **13** are mounted on the same printed wiring board **50**. Hence, compared with a case where the control circuit **12** and the power circuit **13** are mounted on different printed wiring boards, conductors for connecting the different printed wiring boards are unnecessary and therefore the number of necessary connections is reduced. As a result, poor connection is unlikely to occur.

Also, compared with the case where the control circuit **12** and the power circuit **13** are mounted on different printed wiring boards, the overall length of the electrical path can be shortened and therefore injection of radiation noise can be suppressed.

The invention claimed is:

1. A power supply control device, comprising:
  - a power reception terminal for receiving power;
  - a power supply terminal for supplying power;
  - a relay configured to make and break an electrical connection between the power reception terminal and the power supply terminal;
  - a control circuit configured to control the relay;
  - a power supply circuit configured to supply power to the control circuit by use of power received via the power reception terminal;
  - a printed wiring board;
  - an electrical circuit electrically connecting the power reception terminal and the power supply terminal; and
  - a block holding the power reception terminal, the power supply terminal, the relay, the printed wiring board, and the electrical circuit,

wherein:

- the control circuit and the power supply circuit are mounted on the printed wiring board;
- the relay is configured to make and break the electrical connection between the power reception terminal and the power supply terminal by opening and closing the electrical circuit;

the block has a first end and a second end respectively defining opposite ends in a first direction, and a third end and a fourth end respectively defining opposite ends in a second direction perpendicular to the first direction;

the power reception terminal and the power supply terminal are positioned at the first end and the second end, respectively;

the electrical circuit is positioned closer to the third end than the fourth end such that a circuit accommodating space is formed closer to the third end than the fourth end; and

the control circuit and the power supply circuit are positioned in the circuit accommodating space.

## 14

2. The power supply control device according to claim 1, wherein:

the block has a fifth end and a sixth end respectively defining opposite ends in a third direction perpendicular to each of the first direction and the second direction;

the printed wiring board has a mounting surface on which the control circuit and the power supply circuit are mounted; and

the printed wiring board is positioned closer to the sixth end than the fifth end such that the mounting surface faces the fifth end.

3. The power supply control device according to claim 2, wherein:

the block includes a relay accommodating space in which the relay is positioned; and

the relay accommodating space is positioned closer to the fourth end than the third end.

4. The power supply control device according to claim 3, wherein:

the block includes a supporting member supporting the relay;

the supporting member is positioned closer to the sixth end than the fifth end and defines a bottom of the relay accommodating space; and

at least one part of the electrical circuit is embedded in the supporting member.

5. The power supply control device according to claim 3, wherein:

the block includes a partition; and

the partition is interposed between the circuit accommodating space and the relay accommodating space.

6. The power supply control device according to claim 5, wherein:

the block includes a first side wall defining the first end, a second side wall defining the second end, a third side wall defining the third end, and a fourth side wall defining the fourth end;

the circuit accommodating space is defined as a space enclosing by the first side wall, the second side wall, the third side wall, and the partition; and

the relay accommodating space is defined as a space enclosing by the first side wall, the second side wall, the fourth side wall, and the partition.

7. The power supply control device according to claim 1, wherein

the power reception terminal and the power supply terminal are positioned on a straight line extending in the first direction.

8. The power supply control device according to claim 1, wherein:

the power reception terminal is to be electrically connected to an external power source; and

the power supply terminal is to be electrically connected to a charging circuit for charging a battery of an automobile.
